Cryptographic protocols everywhere

Cryptographic protocols

- small programs designed to secure communication (*e.g.* secrecy)
- use cryptographic primitives (*e.g.* encryption, signature,)

• • • • • • • • • •

Protocols and Security

A difficult design:

- Needham-Shroeder protocol (1978), correction and attack by Lowe (1995): an attacker could pretend to be an honest agent.
- Google Single-Sign-On protocol (2008): an attacker can log in to the Google services of a user.
- French e-passport (2010): an attacker can trace a particular user.

Motivation

- Many security properties are equivalence properties: strong secrecy, anonymity, unlinkability...
- Trace equivalence is undecidable in general (and for large subclasses: one variable and choice is enough).

Where does undecidability come from?

Undecidability encodings rely on two key aspects:

- the ability for the protocol to securely forward messages (with honest encryption)
- the ability for the protocol to loop, *i.e.* re-use messages from the end of a session into a new one.
- We need to restrict these properties while keeping our class practical...

Approach

How to find a decidable class of protocols?

- CONCUR'14 to focus on well-typed attacks only,
- dependancy graphs to isolate potential causal dependancies between actions in a well-typed execution,
- prove each well-typed execution is compatible with the dependancy graph,
- consider protocols with acyclic dependancy graph to bound the length of attack traces.

(日) (同) (三) (

The result

Decidability of trace equivalence

Let P and Q be two simple protocols type-compliant w.r.t. some structure-preserving typing systems $(\mathcal{T}_P, \delta_P)$ and $(\mathcal{T}_Q, \delta_Q)$, and with acyclic dependency graphs. The problem of deciding whether P and Q are in trace equivalence (i.e. $P \approx Q$) is decidable.

The result

Decidability of trace equivalence

Let P and Q be two simple protocols type-compliant w.r.t. some structure-preserving typing systems $(\mathcal{T}_P, \delta_P)$ and $(\mathcal{T}_Q, \delta_Q)$, and with acyclic dependency graphs. The problem of deciding whether P and Q are in trace equivalence (i.e. $P \approx Q$) is decidable.

Some intuition:

- simple : protocols with explicit execution flow,
- type-compliant w.r.t. structure-preserving typing sytems : tagged protocols,
- acyclic dependancy graph : no loop for the attacker to abuse.

イロト イポト イヨト イヨト

1 Introduction

2 The model

③ Typing and dependancy graphs

The protocols

- Our primitives: pairs and symmetric encryption.
- We only allow encryption with atomic keys.
- Our grammar:

$$P, Q := 0 \mid \alpha : in(c, u).P \mid \alpha : out(c, u).P \mid (P \mid Q) \mid !P$$

new n.P | new c'.out(c, c').P

$(\alpha : in(c, u).P \cup \mathcal{P}; \phi) \xrightarrow{in(c,R)} (P\sigma \cup \mathcal{P}; \phi)$ where R is a recipe such that $R\phi \downarrow$ is a message and $R\phi \downarrow = u\sigma$ for some σ with $dom(\sigma) = vars(u)$

A D > A B > A B

 $(\alpha: \operatorname{out}(c, u).P \cup \mathcal{P}; \phi) \xrightarrow{\operatorname{out}(c, w_{i+1})} (P \cup \mathcal{P}; \phi \cup \{w_{i+1} \triangleright u\})$ where *u* is a message and *i* is the number of elements in ϕ

(new $c'.out(c, c').P \cup \mathcal{P}; \phi$) $\xrightarrow{out(c, ch_i)}$ ($P\{^{ch_i}/_{c'}\} \cup \mathcal{P}; \phi$) where ch_i is the "next" fresh channel name available in $\mathcal{C}h^{\text{fresh}}$

(new $n.P \cup \mathcal{P}; \phi$) $\xrightarrow{\tau}$ $(P\{n'/n\} \cup \mathcal{P}; \phi)$ where n' is a fresh name in \mathcal{N}

э

A D > A B > A B

$(!P \cup \mathcal{P}; \phi) \xrightarrow{\tau} (P \cup !P \cup \mathcal{P}; \phi)$

2

(ロ) (四) (三) (三)

Equivalences

Static equivalence

 ϕ_1 and ϕ_2 are statically equivalent, $\phi_1 \sim \phi_2$, when $dom(\phi_1) = dom(\phi_2)$ and:

- for any recipe R, $R\phi_1$ is a message iff $R\phi_2\downarrow$ is a message;
- for all recipes R_1 and R_2 such that $R_1\phi_1\downarrow, R_2\phi_1\downarrow$ are messages, we have that $R_1\phi_1\downarrow = R_2\phi_1\downarrow$ iff $R_1\phi_2\downarrow = R_2\phi_2\downarrow$.

A D > A B > A B

Equivalences

Static equivalence

 ϕ_1 and ϕ_2 are statically equivalent, $\phi_1 \sim \phi_2$, when $dom(\phi_1) = dom(\phi_2)$ and:

- for any recipe R, $R\phi_1$ is a message iff $R\phi_2\downarrow$ is a message;
- for all recipes R_1 and R_2 such that $R_1\phi_1\downarrow, R_2\phi_1\downarrow$ are messages, we have that $R_1\phi_1\downarrow = R_2\phi_1\downarrow$ iff $R_1\phi_2\downarrow = R_2\phi_2\downarrow$.

Trace equivalence

A protocol P is trace included in a protocol Q, written $P \sqsubseteq Q$, if for every $(tr, \phi) \in trace(P)$, there exists $(tr', \phi') \in trace(Q)$ such that tr = tr' and $\phi \sim \phi'$. The protocols P and Q are trace equivalent, written $P \approx Q$, if $P \sqsubseteq Q$ and $Q \sqsubseteq P$.

イロト 不得下 イヨト イヨト

Simple protocols

A simple protocol P is a protocol of the form

!new
$$c'_1.out(c_1, c'_1).B_1 | ... |$$
!new $c'_m.out(c_m, c'_m).B_m | B_{m+1} | ... | B_{m+n}$

where each B_i is a ground process on channel c'_i (resp. c_i) built using the following grammar:

$$B := 0 \mid \alpha : in(c'_i, u).B \mid \alpha : out(c'_i, u).B \mid new n.B$$

Moreover, we assume that $c_1, \ldots, c_n, c_{n+1}, \ldots, c_{n+m}$ are pairwise distinct.

Typing and dependancy graphs

э

э

・ロト ・回ト ・ヨト

Structure-preserving typing systems

Typing system

A structure-preserving typing system is a pair $(\mathcal{T}_0, \delta_0)$ where \mathcal{T}_0 is a set of elements called *atomic types*, and δ_0 is a function mapping atomic terms in $\Sigma_0 \cup \mathcal{N} \cup \mathcal{X}$ to types τ generated using the following grammar:

$$\tau, \tau_1, \tau_2 = \tau_0 \mid \langle \tau_1, \tau_2 \rangle \mid \mathsf{enc}(\tau_1, \tau_2) \text{ with } \tau_0 \in \mathcal{T}_0.$$

Then, δ_0 is extended to constructor terms as follows:

$$\delta_0(f(t_1,\ldots,t_n)) = f(\delta_0(t_1),\ldots,\delta_0(t_n))$$
 with $f \in \Sigma_c$.

A D F A A F F

Type-compliant protocols

Type-compliant protocols, ex: tagged protocols

Type-compliant protocols

P is type-compliant w.r.t. (\mathcal{T}, δ) if for every $t, t' \in ESt(unfold^2(P))$,

t and t unifiable $\Rightarrow \delta(t) = \delta(t')$

A D > A B > A B

Example

Denning-Sacco protocol

1. $A \rightarrow S$: A, B2. $S \rightarrow A$: $\{B, K_{ab}, \{K_{ab}, A\}_{K_{bs}}\}_{K_{as}}$ 3. $A \rightarrow B$: $\{K_{ab}, A\}_{K_{bs}}$

The formal specification

$$P = ! \operatorname{new} c_1.\operatorname{out}(c_A, c_1).P_A \mid ! \operatorname{new} c_2.\operatorname{out}(c_B, c_2).P_B \\ \mid ! \operatorname{new} c_3.\operatorname{out}(c_5, c_3).P_5$$

$$P_A = \alpha_1 : \operatorname{out}(c_1, \langle \mathsf{a}, \mathsf{b} \rangle).$$

$$\alpha_2 : \operatorname{in}(c_1, \operatorname{enc}(\langle \mathsf{b}, x_{AB}, x_B \rangle, k_{as})).$$

$$\alpha_3 : \operatorname{out}(c_1, x_B)$$

$$P_B = \beta_1 : in(c_2, enc(\langle y_{AB}, a \rangle, k_{bs})).$$

$$\beta_2 : out(c_2, enc(m_1, y_{AB}))$$

$$P_{S} = \gamma_{1} : in(c_{3}, \langle a, b \rangle). new k_{ab}. \\ \gamma_{2} : out(c_{3}, enc(\langle b, k_{ab}, enc(\langle k_{ab}, a \rangle, k_{bs})\rangle, k_{as}))$$

Example

$$P_A = \alpha_1 : \operatorname{out}(c_1, \langle \mathsf{a}, \mathsf{b} \rangle).$$

$$\alpha_2 : \operatorname{in}(c_1, \operatorname{enc}(\langle \mathsf{b}, x_{AB}, x_B \rangle, k_{as})).$$

$$\alpha_3 : \operatorname{out}(c_1, x_B)$$

$$P_B = \beta_1 : in(c_2, enc(\langle y_{AB}, a \rangle, k_{bs})).$$

$$\beta_2 : out(c_2, enc(m_1, y_{AB}))$$

$$P_{S} = \gamma_{1} : in(c_{3}, \langle a, b \rangle). new k_{ab}. \gamma_{2} : out(c_{3}, enc(\langle b, k_{ab}, enc(\langle k_{ab}, a \rangle, k_{bs})\rangle, k_{as}))$$

the typing function $\boldsymbol{\delta}$

$$\delta(a) = \tau_a \qquad \delta(b) = \tau_b \qquad \delta(m_1) = \tau_m$$

$$\delta(k_{AB}) = \tau_{kab} \qquad \delta(k_{AS}) = \tau_{kas} \qquad \delta(k_{BS}) = \tau_{kbs}$$

$$\delta(x_{AB}) = \tau_{kab} \qquad \delta(y_{AB}) = \tau_{kab}$$

$$\delta(x_B) = \text{enc}(\langle \tau_{kab}, \tau_a \rangle, \tau_{kbs})$$

2

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

Dependancy graph

What is the dependancy graph of P made of?

- Vertices : the labels of P
- Edges : of 3 kinds
 - **(**) sequential dependancy: if two actions follow each other in $P\delta$,
 - **a** data dependancy: if a deducible subterm of an input in $P\delta$ appears as a deducible subterm of an output in $P\delta$,
 - (a) key dependancy: if a key in an output in $P\delta$ can be deduced with the aid of another key, deducible in another ouput in $P\delta$.

 τ_a , τ_b are public types; τ_{kbs} and τ_{kas} are honest types.

A more complex scenario

What happens when A and S communicate with C dishonest $(\alpha'_i \text{ and } \gamma'_i)$ and when B and S talk with C $(\beta''_i \text{ and } \gamma''_i)$?

$$P_B'' = \beta_1'': in(c_2, enc(\langle y_{CB}, c \rangle, k_{bs})).$$

$$P_S'' = \gamma_1: in(c_3, \langle c, b \rangle). new \ k_{cb}.$$

$$\gamma_2'': out(c_3, enc(\langle b, k_{cb}, enc(\langle k_{cb}, c \rangle, k_{bs})\rangle, k_{cs}))$$

The result

Decidability of trace equivalence

Let *P* and *Q* be two simple protocols type-compliant w.r.t. some structure-preserving typing systems $(\mathcal{T}_P, \delta_P)$ and $(\mathcal{T}_Q, \delta_Q)$, and with acyclic dependency graphs. The problem of deciding whether *P* and *Q* are in trace equivalence (i.e. $P \approx Q$) is decidable.

Denning-Sacco and Wide-Mouthed Frog fall into this class.

Refined dependancy graph

How to deal with these acyclic graphs?

- introduce a (semantic) notion of marking to pinpoint terms which are useless to the attacker,
- propose a (syntactic) criterion to generate such markings in practice,
- and use a refined notion of the dependancy graph.

The (refined) result

Decidability of trace equivalence

Let P and Q be two simple protocols type-compliant w.r.t. some structure-preserving typing systems $(\mathcal{T}_P, \delta_P)$ and $(\mathcal{T}_Q, \delta_Q)$, and with acyclic refined dependency graphs. The problem of deciding whether P and Q are in trace equivalence (i.e. $P \approx Q$) is decidable.

	Dependency graph		In our
	Normal	Refined	class
Denning-Sacco	\checkmark	\checkmark	yes
Needham-Schroeder		\checkmark	yes
Otway-Rees		\checkmark	yes
Yahalom (Paulson)		\checkmark	yes
Wide-Mouthed-Frog	\checkmark	\checkmark	yes
Yahalom			no
Kao-Chow (modified)		\checkmark	yes

Figure : A \checkmark means that the corresponding dependency graph is acyclic.

Proof outline

Our proof can be summarised as follows:

- We first rely on our type-compliance assumption. We show that we can restrict our attention to witnesses that are well-typed and we further show that each message occurring in such a trace can be computed as soon as possible.
- Then, we show that all the dependencies occurring in such a well-typed and asap trace comply with the dependency graph. Hence, we bound the width as well as the depth of such a witness exploiting the acyclicity of our dependency graph.
- Substitution and the set of a minimal witness:

 $2(1 + \|\mathsf{out}_{\mathcal{P}}\|)^{\mathsf{depth}(\mathcal{G}_{\mathcal{P}})+1}(1 + \|\mathsf{in}_{\mathcal{P}}\|(1 + \|\mathsf{out}_{\mathcal{P}}\|)^{\mathsf{depth}(\mathcal{G}_{\mathcal{P}})+1})^{\mathsf{depth}(\mathcal{G}_{\mathcal{P}})+1}.$

イロト 不得下 イヨト イヨト

Conclusion

We obtained:

- a decidability result for equivalence of simple acyclic type-compliant protocols,
- which extends existing results for reachability;
- along with syntactic/semantic criterion to easily obtain acyclic protocols,
- and most of the studied examples fall into this class.

< 口 > < 同 >

What remains to be done:

- extend our signature to asymmetric cryptography,
- relax the hypothesis of simple protocols (to action-determinate)
- implement a tool to automatically compute et verify the acyclicity of any protocol.
