# Games for Synthesis (of Reactive Systems)

---

👉 support the design process with **automatic synthesis**

- Sys is constructed by an algorithm
- Sys is **correct** by construction
- Underlying theory: **2-player zero-sum games**
- Env is **adversarial** (worst-case assumption)

**Correct Sys = Winning strategy**

# Plan of the talk

# 2-player zero sum games on graphs

# Games played on graphs

Arena

Start with pebble on initial vertex

Repeat for  $\infty$ -many rounds:

➔ The player that owns the current vertex moves the pebble to an adjacent vertex

Interaction → **infinite path** = a **play**

**Winning condition**  $W \subseteq V^\omega$  for Player 1

= set of plays

$V^\omega \setminus W$  is winning for Player 2 (zero-sum).

Outcome=Play=1 - 4 - 5 - 3 - 1 - 2 - ...

(Player 1) **Winning condition**: cross “2” and “5”  $\infty$ -often

# Games played on graphs

# Strategies

---

**Strategy for Player I =**  
One choice in each node of Player I  
in tree unfolding

$$\lambda_I: V^* \cdot V_I \rightarrow \text{edge}$$

Strategy is **winning**  
(for Player I),  
if **all** branches of the resulting  
tree in the winning condition

# Types of strategies

## (Player I) strategy:

$\lambda_I: V^*.V_I \rightarrow \text{edge.}$

$\Sigma_I = \text{set of strategies of Pl. I}$

## Memoryless strategy:

$\lambda_{I,m}: V_I \rightarrow \text{edge.}$

$\Sigma_{I,m} = \text{set of memoryless strategies of Player I}$

## Finite-memory strategy:

$\lambda_{I,f}: V^*.V_I \rightarrow \text{edge}$  but **regular** (Moore machine)

$\Sigma_{I,f} = \text{set of finite memory strategies of Player I}$

## Randomized strategy:

$\lambda_{I,m}: V^*.V_I \rightarrow \mathbf{Dist}(\text{edge}).$

$\Sigma_{I,m} = \text{set of randomized strategies of Player I}$

# Typical questions

---

- ▶ **Types of objectives** (winning conditions) that ensures that one player wins or the other - **determinacy** ?  
General result: Borel determinacy [Martin73].
- ▶ **Types of strategies** necessary to win ?
  - ▶ How much memory is needed ?
  - ▶ Do we need randomization ?  
(this is necessary for example when considering concurrent moves or imperfect information)
- ▶ **Complexity** of deciding the winner ...
- ▶ **Efficient algorithms** to construct winning strategies ...

# Need for richer models

---

From

2-player games	Sys <b>versus</b> Env
Zero sum games	Env is <b>antagonist</b>
Boolean objectives	Winning <b>or</b> losing
Perfect information	Sys observes Env <b>perfectly</b>

To

N-player games	Modern systems are made of <b>components</b>
Non-zero sum	Components have <b>their own objectives</b>
 Quantitative objectives	Need to <b>compare</b> different solutions
Imperfect information	Components have a <b>partial view</b> of the system

# Mean-Payoff Games [EM79]

: positions of **maximizer=system**

: positions of **minimizer=environment**

Edges are labelled with rewards

(1,4) (4,5) (5,4) ... (4,5) (5,4) ... =play  
4 3 -1 3 -1 ...

$$= \mathbf{Lim Sup}_{n \rightarrow +\infty} \sum_{i=1, i=n} r_i / n = 1.$$

$$= \mathbf{MP}((1,4) (4,5) (5,4) \dots (4,5) (5,4) \dots)$$

**Win** = { play | MP(play)  $\geq$  **c** }

Note: **not**  $\omega$ -regular.

# Mean-Payoff Games [EM79]

**Outcome** $(s, \lambda_1, \lambda_2)$  = infinite sequence of edges when players play  $\lambda_1$  and  $\lambda_2$  from  $s$ .

The value of the game in  $s$  under  $\lambda_1$  and  $\lambda_2$  is

**MP** $(\text{Outcome}(s, \lambda_1, \lambda_2))$ .

**The decision problem for mean-payoff games** asks given an initial state  $s$  if Maximizer has a **strategy** to ensure a mean-payoff greater or equal to a integer value  $v$  from  $s$  no matter what Minimizer plays.

# Energy Games [CdAHS03,BFLMS08]

○ : positions of **maximizer**  
 □ : positions of **minimizer**

Edges are labelled with energy consumptions or energy gains.

Strategies are defined as for MPG.

Initial energy level : **7**

Play : (1,2) (2,1) (1,4) (4,5) (5,4) (4,5) (5,4) ...

**EL** : **7** 8 3 7 10 9 10 9 ...

---

⊨ □ **EL** ≥ 0

# Energy Games [CdAHS03,BFLMS08]

---

The **decision problem for energy games** asks given an initial state  $s$  if **there exist**

★ an **initial energy level**

★ and  $\lambda_1$  **for Maximizer** to maintain a positive energy level at all time ( $\square \mathbf{EL} \geq 0$ ), no matter what Minimizer plays.

# Energy Games [CdAHS03,BFLMS08]

The **decision problem for energy games** asks given an initial state  $s$  if **there exist**

★ an **initial energy level**

★ and  $\lambda_1$  **for Maximizer** to maintain a positive energy level at all time ( $\square \mathbf{EL} \geq 0$ ), no matter what Minimizer plays.

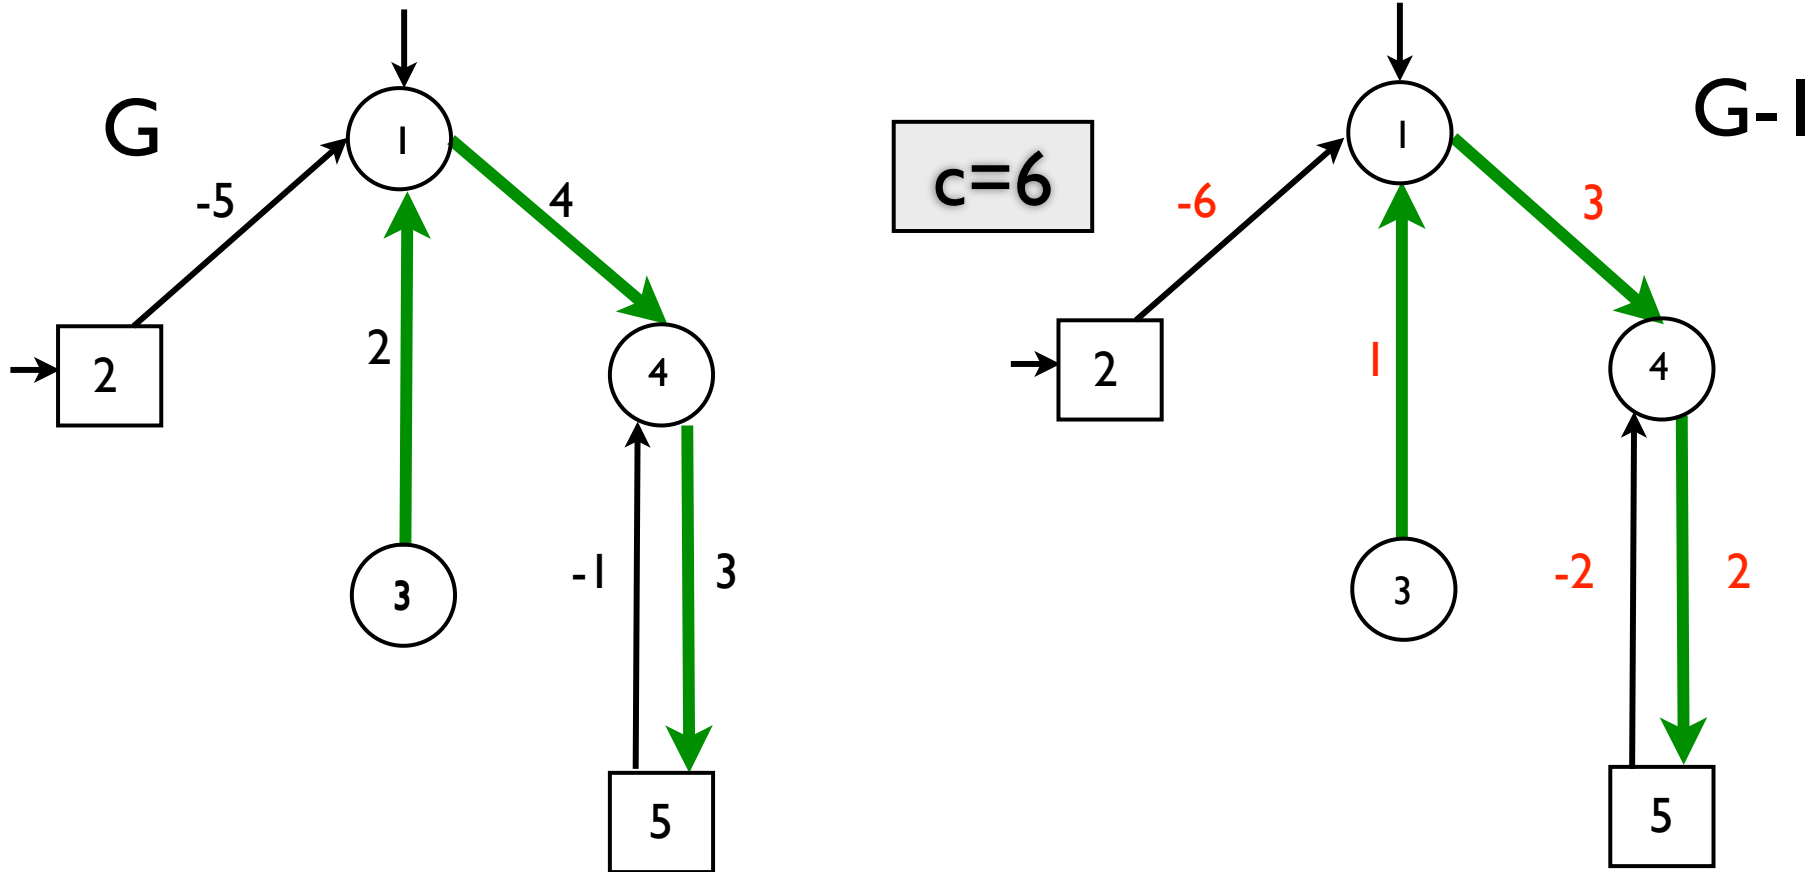

**Thm.** Maximizer enforces value at least  $v$  in MPG  $G$  iff Maximizer has a winning strategy in the ENG  $G-v$ .

# MPGs and EGs [BFLMS08]

Maximizer ensure value 1 in MPG **iff** Maximizer win EG G-1.

# MPGs and EGs [BFLMS08]

MPGs and EGs are **memoryless** determined and in  **$NP_{\cap coNP}$**

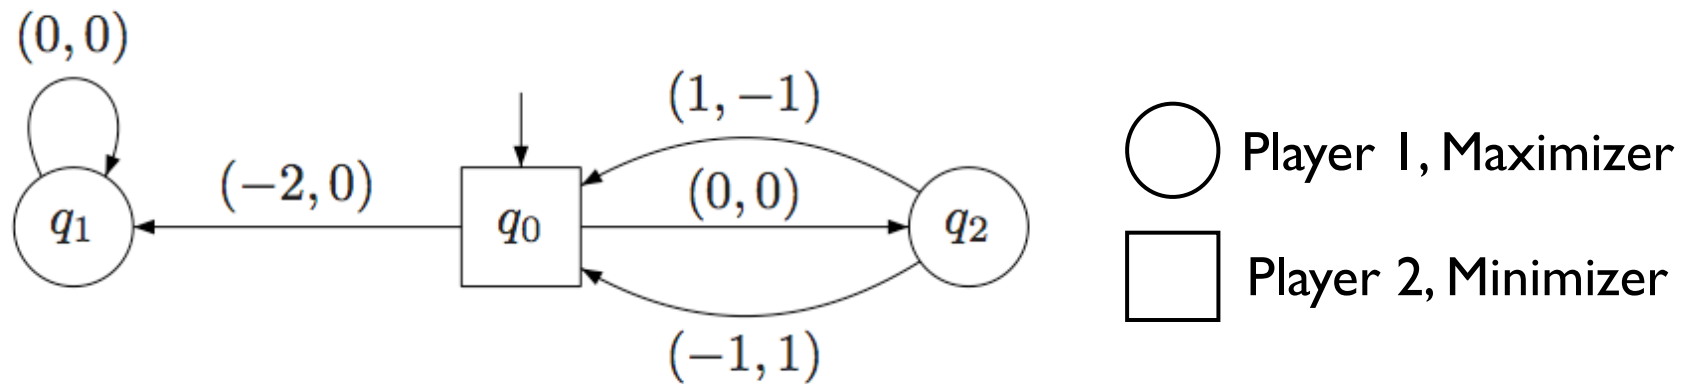

# Generalization - Motivations

---

We study here **multi-dimensional** extensions of energy and mean-payoff games:

- Useful for modeling control problems for embedded systems with **multiple** quantitative aspects;
- We study “under **which sets of strategies** are those games determined ?”
- We settle open **complexity** questions.

# Generalized Energy Games (gEGs)

?  $\exists (C_1, C_2) \in \mathbb{N}^2$  and  $\lambda_1$  s. t. **Outcome**( $q_0, \lambda_1, (C_1, C_2)$ )  $\models$   $\square \mathbf{EL}_1 \geq 0 \wedge \mathbf{EL}_2 \geq 0$ .

Memory

# Generalized Energy Games (gEGs)

?  $\exists (C_1, C_2) \in \mathbb{N}^2$  and  $\lambda_1$  s. t. **Outcome**( $q_0, \lambda_1, (C_1, C_2)$ )  $\models$   $\square \mathbf{EL}_1 \geq 0 \wedge \mathbf{EL}_2 \geq 0$ .

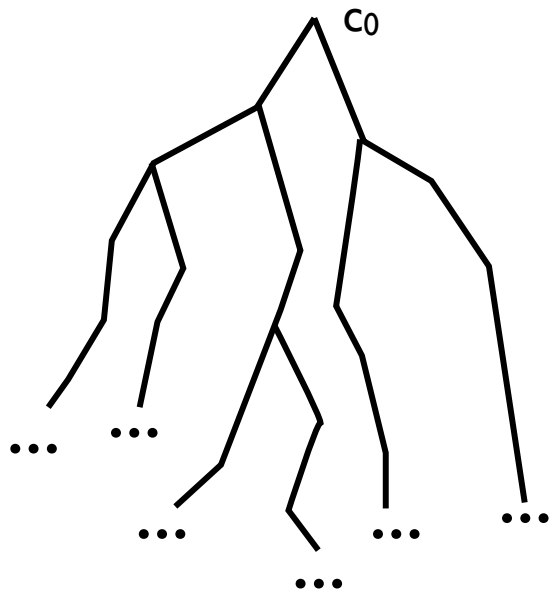

- For any  $(C_1, C_2) \geq (2, 1)$ , Player 1 has a winning strategy.
- Player 1 needs memory ! How much ?

# Player I - Finite Memory Strategies

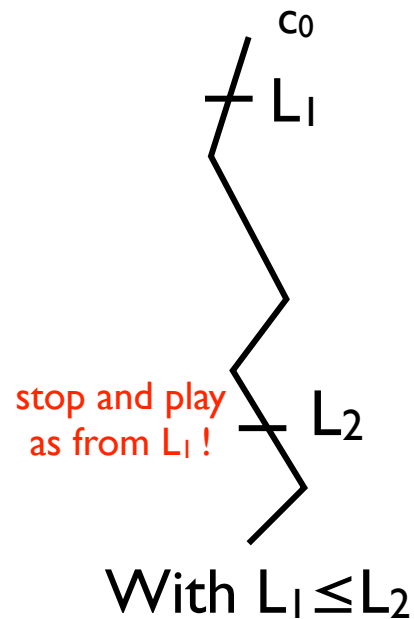

**Lemma.** Finite memory strategies are sufficient for Player I to win in gEGs.

**Proof.** First, remember that  $(\mathbb{N}^k, \leq)$  is well-quasi ordered.

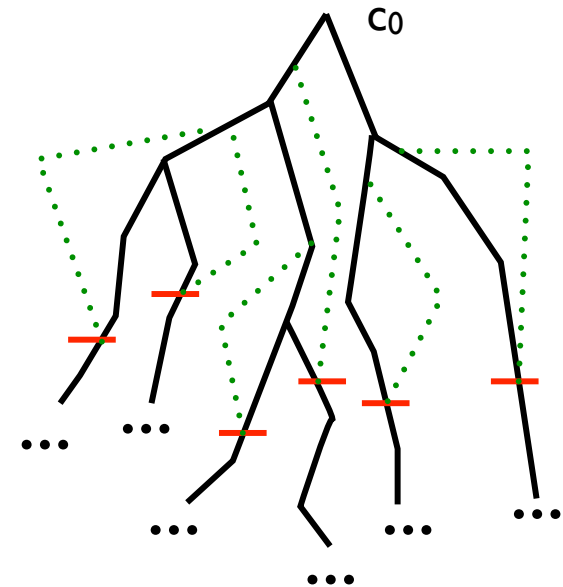

Let  $\lambda_I$  be winning

On each branch

Then  $\lambda'_I$  is winning and finite memory

wqo+Koenig's lemma

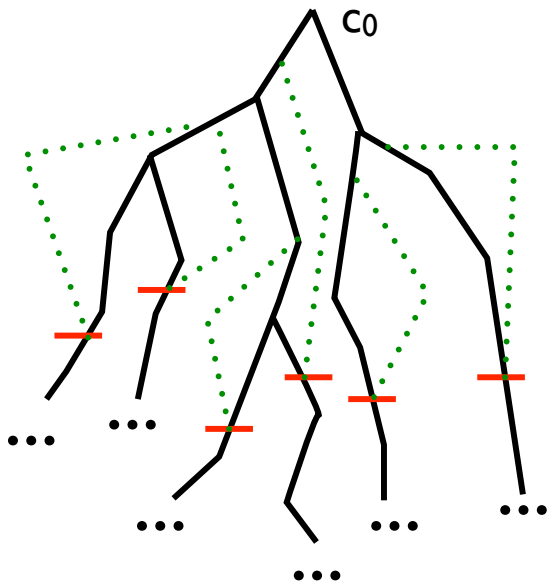

# Player I - Finite Memory Strategies

---

**Lemma.** Finite memory strategies are sufficient for Player I to win in gEGs.

**Proof.** First, remember that  $(\mathbb{N}^k, \leq)$  is well-quasi ordered.

Then  $\lambda'_I$  is winning  
and finite memory

wqo+Koenig's lemma

Finite tree=winning strategy:

- ① play according to the choices made in tree
- ② in leaf, go to ancestor with lower energy

# Finite memory $\rightarrow$ Exponential memory

---

Then  $\lambda'_1$  is winning  
and finite memory

wqo+Koenig's lemma

① Exponential memory is sufficient.

- Use extensions of technics à la Rackoff (Petri nets) - refinements of [BJK10]

② Exponential memory is needed

③ Leads to symbolic and incremental algorithms

Finite

# gMPGs - Infinite Memory

---

To play optimally gMPGs, infinite memory is necessary

Consider the strategy that alternates visits to  $q_a$  and  $q_b$  such that after the  $n^{\text{th}}$  alternation, the self-loop on the visited state  $q$  ( $q \in \{q_a, q_b\}$ ) is taken **so many times** that the average frequency of  $q$  gets larger than  $(n-1)/n$  in the current finite prefix of the play. This is always possible and achieves threshold  $(2, 2)$  for Lim Sup MP.

# Player 2 - Memoryless Strategies

---

gEGs are particular cases of “zero-games” played on **vector addition systems extended with states** (VASS).

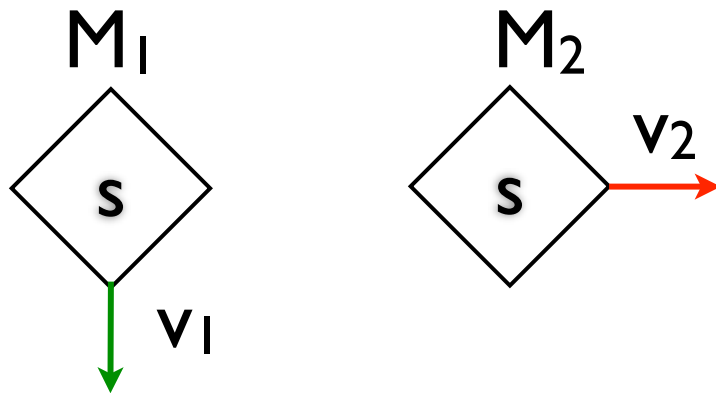

For such games, [BrazdilJancarKuncera10] establishes that **memoryless** strategies are sufficient for Player 2.

**Lemma**[BJK10]. Memoryless strategies are sufficient for Player 2 to win in “zero-games” played on VASS.

# Player 2 - Memoryless - Why ?

**Intuition:** Player 2 cannot play better if he knows the energy levels.

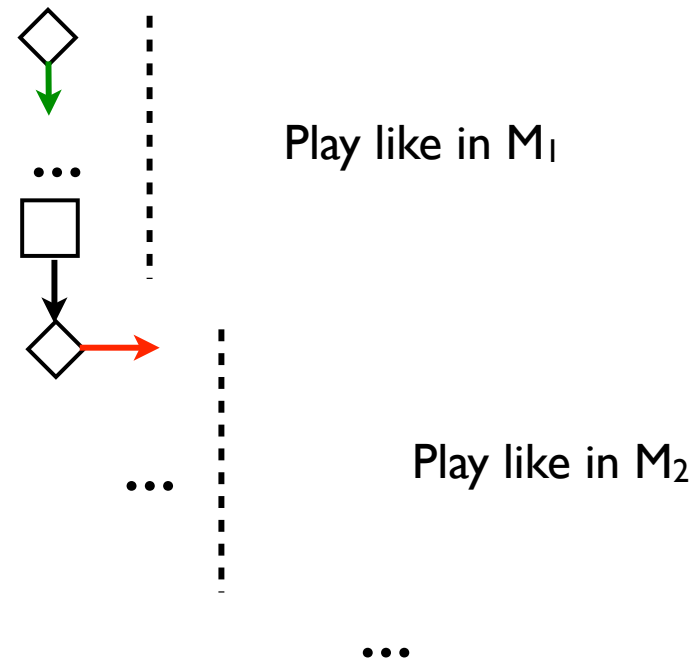

If

Then

Strategy for Player 1  
alternates  
when Player 2 changes in  $s$

# Player 2 - Memoryless Strategies

---

gEGs are particular cases of “zero-games” played on **vector addition systems extended with states (VASS)**.

For such games, [BrazdilJancarKuncera10] establishes that **memoryless** strategies are sufficient for Player 2.

**Lemma**[BJK10]. Memoryless strategies are sufficient for Player 2 to win in “zero-games” played on VASS.

**Theorem**[BJK10]. Zero-game played on vector addition systems extended with state can be solved in **ExpSpace**.

**Corollary**. The unknown initial credit problem in gEGs is in **ExpSpace**.

Complexity

# Complexity of gEGs

---

- Memoryless strategies are sufficient for Player 2 to win a gEG  $G$ .
- Let  $\lambda_2 \in \Sigma_{2,m}$ ,  $G(\lambda_2)$  is a multi-weighted graph.
- $\lambda_2$  is losing **iff**  $G(\lambda_2)$  contains a reachable cycle (not necessarily simple) with positive effect on all dimensions.

# Complexity of gEGs

---

- Memoryless strategies are sufficient for Player 2 to win a gEG  $G$ .
- Let  $\lambda_2 \in \Sigma_{2,m}$ ,  $G(\lambda_2)$  is a multi-weighted graph.
- $\lambda_2$  is losing **iff**  $G(\lambda_2)$  contains a reachable cycle (not necessarily simple) with positive effect on all dimensions.

**Theorem**[Kosaraju,Sullivan88]. Given a multi-weighted graph  $G$ , it is decidable in deterministic polynomial time if  $G$  contains a state  $s$  which is reachable from itself with a (not necessarily simple) path with zero effect on all dimensions.

# Complexity of gEGs

---

- Memoryless strategies are sufficient for Player 2 to win a gEG  $G$ .
- Let  $\lambda_2 \in \Sigma_{2,m}$ ,  $G(\lambda_2)$  is a multi-weighted graph.
- $\lambda_2$  is losing **iff**  $G(\lambda_2)$  contains a reachable cycle (not necessarily simple) with positive effect on all dimensions.

**Lemma.** The unknown initial credit problem in gEGs belongs to coNP.

# Complexity of gEGs

---

**Lemma.** The unknown initial credit problem in gEGs is coNP-Hard.

**Proof.** We show that deciding whether **Player I has a winning strategy** is as hard as deciding if a 3CNF formula is **unsatisfiable**.

Let  $\psi$  be a 3CNF formula with clauses  $C_1, C_2, \dots, C_k$  over variables  $\{x_1, x_2, \dots, x_n\}$ . We construct from  $\psi$  the following game structure with weight in  $\mathbb{Z}^{2n}$ :

# Complexity of gEGs

---

$$\text{Ex: } \Phi = (x \vee \neg y \vee z) \wedge (\neg x \vee y \vee \neg z)$$

# Complexity of gEGs

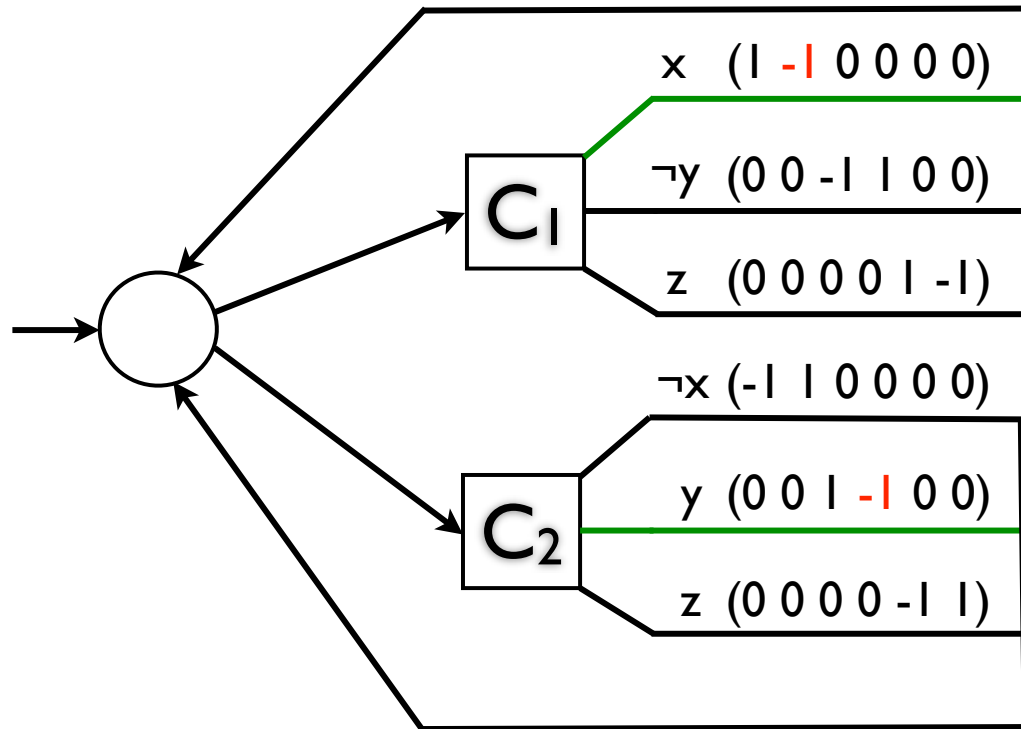

Ex:  $\Phi = (x \vee \neg y \vee z) \wedge (\neg x \vee y \vee \neg z)$

We define the weight labeling as follows:

- every edge is labeled by  $\{0\}^{2n}$  with the exception of edges going from literals back to initial state.
- for a literal  $y$  and an edge back to the initial state, the weight vector contains:
  - $1$  in the dimension of  $y$
  - $-1$  in the dimension of the complement of  $y$
  - $0$  otherwise

# Complexity of gEGs

Ex:  $\Phi = (x \vee \neg y \vee z) \wedge (\neg x \vee y \vee \neg z)$

$v(x)=1, v(y)=1, v(z)=0$

$v \models \Phi$

$\lambda_2(C_1)=x$

$\lambda_2(C_2)=y$

**$\Phi$  is satisfiable implies Player 2 wins**

Let  $v$  be s.t.  $v \models \Phi$ . We construct  $\lambda_2$  as follows: in each clause  $C_i$ ,  $\lambda_2$  chooses  $l_{ij}$  s. t.  $v \models l_{ij}$ . Now, take any  $\lambda_1$  and consider the play consistent with  $\lambda_1$  and  $\lambda_2$ . There must exist  $C_i$  that appears  $\infty$ -often along this play: **the dimension that correspond to  $\neg l_{ij}$  is decreased  $\infty$ -often without ever being increased** ! There is no initial credit that can help Player 1 !

# Complexity of gEGs

**$\Phi$  is unsatisfiable implies Player 1 is winning**  
or equivalently  **$\Phi$  is unsatisfiable implies Player 2 is not winning**

As  $\Phi$  is unsatisfiable, when Player 2 chooses one literal per clause (we know that he can play optimally without memory), it has to choose two literals that are **complementary**. Let assume that the choice of Player 2 are complementary for clauses  $C_i$  and  $C_j$ . In that case, the winning strategy for Player 1 is to alternate between  $C_i$  and  $C_j$ . This strategy is winning for a initial credit of 1 in all dimension.

$$\Phi = (\neg y) \wedge (x \vee y) \wedge (\neg x)$$

# Complexity of gEGs

**$\Phi$  is unsatisfiable implies Player 1 is winning**  
or equivalently  **$\Phi$  is unsatisfiable implies Player 2 is not winning**

As  $\Phi$  is unsatisfiable, when Player 2 chooses one literal per clause (we know that he can play optimally without memory), it has to choose two literals that are **complementary**. Let assume that the choice of Player 2 are complementary for clauses  $C_i$  and  $C_j$ . In that case, the winning strategy for Player 1 is to alternate between  $C_i$  and  $C_j$ . This strategy is winning for a initial credit of 1 in all dimension.

$$\Phi = (\neg y) \wedge (x \vee y) \wedge (\neg x)$$

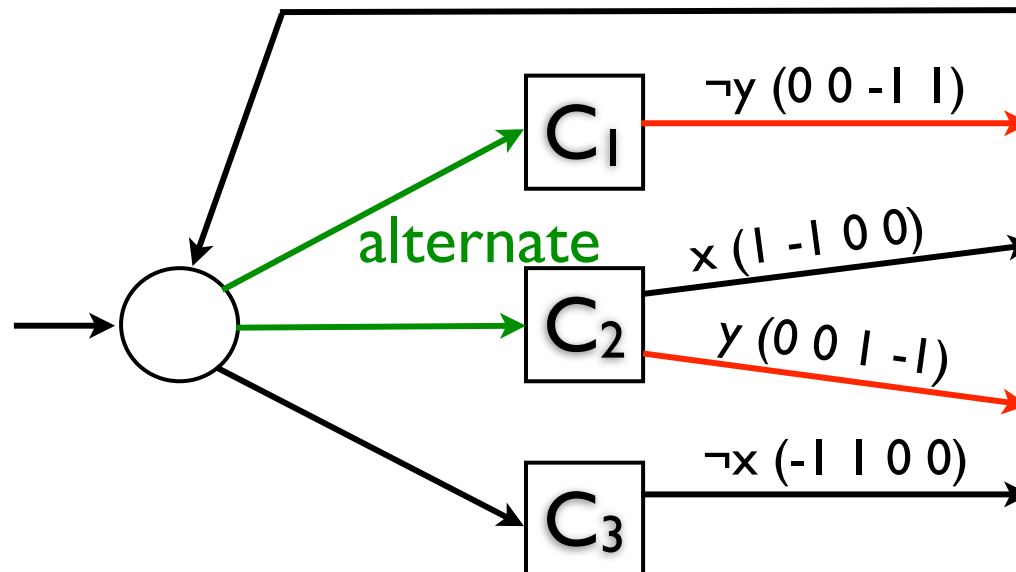

# Complexity of gEGs

$\Phi$  is unsatisfiable implies Player 1 is winning  
or equivalently  $\Phi$  is unsatisfiable implies Player 2 is not winning

As  $\Phi$  is unsatisfiable, when Player 2 chooses one literal per clause (we know that he can play optimally without memory), it has to choose two literals that are **complementary**. Let assume that the choice of Player 2 are complementary for clauses  $C_i$  and  $C_j$ . In that case, the winning strategy for Player 1 is to alternate between  $C_i$  and  $C_j$ . This strategy is winning for a initial credit of 1 in all dimension.

$$\Phi = (\neg y) \wedge (x \vee y) \wedge (\neg x)$$

$$\begin{aligned} & (0 \ 0 \ -1 \ 1) \\ & + \\ & (0 \ 0 \ 1 \ -1) \\ & = \\ & (0 \ 0 \ 0 \ 0) \end{aligned}$$

# Complexity of gEGs

---

**Theorem.** The unknown initial credit problem in gEGs is **coNP-C**.

Trading memory for  
randomness

# Trading memory for randomness

---

First, an example: Mean-payoff + Büchi game

Value 1 requires **infinite memory**

Value  $1-\epsilon$  possible with finite (**exponential** in  $\epsilon$ ) memory.

Exponential memory strategy can be replaced by a memoryless **randomized** strategy:  $1-\epsilon$  is reached with **probability 1**.

# Trading memory for randomness

---

Combine two types of strategies:

- (i) **Good for payoff** and (ii) **Good for Büchi** (F-attractor)

Both are **memoryless**

To play optimally, frequency of **Good for payoff** must strictly increase and tend to 1 but **Good for Büchi** played  $\infty$ -often.

To play  $\epsilon$ -optimally, frequency of **Good for payoff** =  $1 - (\epsilon/2)$

☞ either **count** or use **randomization**

# Trading memory for randomness

---

**Theorem.** In (1-dim) **mean-payoff parity games**,  $\epsilon$ -optimality can be achieved either using

- a finite (exponential) memory strategy, or
- a memoryless randomized strategy

Randomization does not help in energy games (safety).

# Summary
