# Introduction

Infinite duration games are useful:

- verification;
- synthesis.

Goal: transform infinite duration games into finite duration ones.

Zero-sum games are well known. It's not the case of non-zero-sum games.

# Introduction: the problem with non-zero-sum games

Impossibility to make assumptions about the strategies used by the players

Players could:

- play as in zero-sum games;
- cooperate;
- voluntary loose...

This raises problems for our transformation. The solution is our main contribution: the power matrix.

## About games

A *game* is constituted of a *game graph* and conditions that the players want to ensure.

A *play* is a sequence of positions in a game.

A *strategy* for a player is a function which let the player know what he has to do at his turn.

# Plan

- 1 First intuition: use outcome equivalence
- 2 Too many equivalence classes
  - Fundamental lemma
  - Proof and remarks
- 3 Our solution: the power matrix
  - Power matrix and power graph
  - How to use power matrix

# Intuition

Represent a 2-player game  $G$  as a matrix where:

- the rows and the columns are strategies;
- the entries are the associated outcomes.

Each player chooses a strategy. The outcome is the entry corresponding to the chosen row and the chosen column.

In fact, the strategies in this matrix correspond to equivalence classes over strategies in  $G$ .

For  $n$  players the matrix will have  $n$  dimensions.

# Outcome equivalence

Strategies should be equivalence classes for the following equivalence relation:

## Outcome equivalence

Two strategies  $s^i$  and  $r^i$  are *outcome equivalent*  $\iff \forall s^{-i}$ , the only play consistent with the profile of strategies  $(s^i, s^{-i})$  has exactly the same outcome as the only play consistent with the profile of strategies  $(r^i, s^{-i})$ .

To be usable, the matrix has to be finite.

## A problematic observation

### Lemma

There exist games with infinitely many strategies that are not outcome equivalent.

Due to this, it is, in general, impossible to construct a finite matrix as described before.

## Proof and remarks

The idea of the proof is to construct:

- an infinite sequence of strategies for player 0;
- a corresponding sequence of strategies for player 1;

such that it is easy to show that all these strategies are in different equivalence classes.

The proof is only based on the structure of the game graph.

# The case of zero-sum games

# Power matrix

The *power matrix* of a game  $G$  is a matrix:

- the rows and the columns are called power strategies;
- the entries are sets of outcomes associated to these strategies.

Power strategies correspond to equivalence classes for a given equivalence.

# Power matrix

The equivalence used is based on sets of outcomes, not only singletons.

## Lemma

The power matrix of every game is finite.

Proved just by counting the sets of outcomes.

# Power graph

A *power graph* is a graph representation of a power matrix.

- *Imperfect information* represents that the players choose their strategies at the same time.
- *Non-determinism* is used to choose an outcome in the final set of outcomes.

# Power matrix and power graph: example

	$\{a, b\}$	$\{\infty, b\}$	$\{\infty, a, b\}$
$\{a, \infty\}$	$\{a\}$	$\{\infty\}$	$\{\infty\}$
$\{a, \infty, b\}$	$\{a, b\}$	$\{\infty\}$	$\{\infty\}$
$\{b\}$	$\{b\}$	$\{b\}$	$\{b\}$
$\{a, b\}$	$\{a, b\}$	$\{b\}$	$\{a\}$

# Power matrix and power graph: example

	$\{a, b\}$	$\{\infty, b\}$	$\{\infty, a, b\}$
$\{a, \infty\}$	$\{a\}$	$\{\infty\}$	$\{\infty\}$
$\{a, \infty, b\}$	$\{a, b\}$	$\{\infty\}$	$\{\infty\}$
$\{b\}$	$\{b\}$	$\{b\}$	$\{b\}$
$\{a, b\}$	$\{a, b\}$	$\{b\}$	$\{a\}$

# Replacing components

Components of a game can be replaced by power graphs.

# The new game graph

## Our contribution

We introduced:

- the concept of power matrix and power graph;
- the method of replacing components of a game.

We also applied these to *guarantee games*.

The *dominance relation* between strategies is preserved by the replacement of components.

## Further work

Replace components in:

- non-zero-sum games, like parity games;
- games with imperfect information.
